## ABSTRACT

An experimental investigation of the transition process on flat-plate and concave curved-wall boundary layers for various free-stream turbulence levels was performed. Where possible, sampling according to the intermittency function was made. Such sampling allowed segregation of the signal into two types of behavior-laminar-like and turbulent-like. Results show that for transition on a flat-plate, the two forms of boundary layer behavior, identified as laminar-like and turbulent-like, cannot be thought of as separate Blasius and fully-turbulent profiles, respectively. Thus, simple transition models in which the desired quantity is assumed to be an average, weighted on intermittency, of the theoretical laminar and fully turbulent values is not expected to be successful. Deviation of the flow identified as laminar-like from theoretical laminar behavior is shown to be due to recovery after the passage of a turbulent spot, while deviation of the flow identified as turbulent-like from the fully-turbulent values is thought to be due to incomplete establishment of the fully-turbulent power spectral distribution. Turbulent Prandtl numbers for the transitional flow, computed from measured shear stress, turbulent heat flux and mean velocity and temperature profiles, were less than unity. For the curved-wall case with low free-stream turbulence intensity, the existence of Görtler vortices on the concave wall within both laminar and turbulent flows was established using liquid crystal visualization and spanwise velocity and temperature traverses. Transition was found to occur via a vortex breakdown mode. The vortex wavelength was quite irregular in both the laminar and turbulent flows, but the vortices were stable in time and space. The upwash was found to be more

unstable, with higher levels of  $u'$  and  $u'v'$ , and lower skin friction coefficients and shape factors. Turbulent Prandtl numbers, measured using a triple-wire probe, were found to be near unity for all post-transitional profiles, indicating no gross violation of Reynolds analogy. No evidence of streamwise vortices was seen in the high turbulence intensity case. It is not known whether this is due to the high eddy viscosity over the entire flow which reduces the turbulent Görtler number to stable values and causes the vortices to disappear, or whether it is due to an unstable vortex structure. Predictions based on two-dimensional modelling of the flow over a concave wall with high free-stream turbulence levels, as on the pressure surface of a turbine blade, would seem to be adequate. High levels of free-stream turbulence superimposed on a free-stream velocity gradient (which occurs within curved channels) was found to cause a cross-stream transport of momentum within the "potential core" of the flow. The total pressure within the "potential core" can thus rise to levels higher than that which occurs at the inlet to the test section.

Documentation is presented in two volumes. Volume I contains the text of the report including figures and supporting appendices. Volume II contains data reduction program listings and tabulated data.

## **ACKNOWLEDGEMENTS**

The following work was sponsored by the Lewis Research Center of NASA under grant NASA/NAG3-881. The authors thank the grant monitor, Mr. Fred Simon, for his guidance.

Some additional support was provided by the Air Force Office of Scientific Research and the Graduate School of the University of Minnesota.

## TABLE OF CONTENTS

### VOLUME II

A4. Program Listings	1
A5. Data Listings	
Case 1-Low TI, Flat-wall	75
Case 2-Medium TI, Flat-wall	125
Case 3-High TI, Flat-wall	181
Case 4-Low TI, Concave Curved Wall	206
Case 5-High TI, Concave Curved Wall	246

#### A.4 Program Listing

- 1). STANTON: Program for measuring Stanton numbers using the embedded thermocouples in the wall. (p. 174)
- 2). VRED\_CW: Reduction program for velocity measurements in the curved-wall configuration. For flat-wall measurements, used a large wall radius. (p. 189)
- 3). TRED\_CW: Reduction program for temperature measurements. (p. 200)
- 4). UVRED\_CW: Reduction program for X-wire measurements. (p. 216)
- 5). K2H01H02: Program for finding empirical constant needed for frequency compensation of cold-wire in triple-wire measurements. (p. 223)
- 6). VTACQ: Acquisition program for triple-wire measurements. (p. 230)
- 7). I\_VTRED: Reduction program for triple-wire measurements (p. 234)

20 ! DATA REDUCTION PROGRAM FOR VELOCITY ON CONCAVE CURVED WALL (URED_CW)
30 ! THIS PROGRAM PERFORMS THE FOLLOWING:
40 !   1). CALCULATES Delta1, Delta2, H and Delta from the velocity profile
      on disc. Correction for curvature is made.
50 !   2). CALCULATES and PLOTS U/Uinf vs. Y/Delt1. Data normalized on
      local potential velocity (not Upw).
60 !   3). CALCULATES Cf from Uplus vs. Yplus data. The Clauser technique
      is used in the turbulent region. Uplus vs. Yplus is plotted.
70 !      Data is normalized on local potential velocity (not Upw).

30 ! DATA REDUCTION PROGRAM FOR TEMPERATURE (TRED_CW)
40 ! THIS PROGRAM PERFORMS THE FOLLOWING:
50 !   1). CALCULATES Del_th, Del_enth, and Del_cond from the velocity and
      temperature profiles on disc.
60 !   2). CALCULATES and PLOTS (Tw-T)/(Tw-Tinf) vs. Y/Del_th.
70 !   3). CALCULATES Prt from Tplus vs. Yplus data. The Clauser technique
      is used in the turbulent region. Tplus vs. Yplus is plotted.
80 !   4). Curvature correction for velocity is made.

16. Abstract <p>An experimental investigation of the transition process on flat-plate and concave curved-wall boundary layers for various free-stream turbulence levels was performed. Where possible, sampling according to the intermittency function was made. Such sampling allowed segregation of the signal into two types of behavior—laminar-like and turbulent-like. Results show that for transition on a flat-plate, the two forms of boundary layer behavior, identified as laminar-like and turbulent-like, cannot be thought of as separate Blasius and fully-turbulent profiles, respectively. Thus, simple transition models in which the desired quantity is assumed to be an average, weighted on intermittency, of the theoretical laminar and fully turbulent values is not expected to be successful. Deviation of the flow identified as laminar-like from theoretical laminar behavior is shown to be due to recovery after the passage of a turbulent spot, while deviation of the flow identified as turbulent-like from the fully-turbulent values is thought to be due to incomplete establishment of the fully-turbulent power spectral distribution. Turbulent Prandtl numbers for the transitional flow, computed from measured shear stress, turbulent heat flux and mean velocity and temperature profiles, were less than unity. For the curved-wall case with low free-stream turbulence intensity, the existence of Görtler vortices on the concave wall within both laminar and turbulent flows was established using liquid crystal visualization and spanwise velocity and temperature traverses. Transition was found to occur via a vortex breakdown mode. The vortex wavelength was quite irregular in both the laminar and turbulent flows, but the vortices were stable in time and space. The upwash was found to be more unstable, with higher levels of <math>u'</math> and <math>u'v'</math>, and lower skin friction coefficients and shape factors. Turbulent Prandtl numbers, measured using a triple-wire probe, were found to be near unity for all post-transitional profiles, indicating no gross violation of Reynolds analogy. No evidence of streamwise vortices was seen in the high turbulence intensity case. It is not known whether this is due to the high eddy viscosity over the entire flow which reduces the turbulent Görtler number to stable values and causes the vortices to disappear, or whether it is due to an unstable vortex structure. Predictions based on two-dimensional modelling of the flow over a concave wall with high free-stream turbulence levels, as on the pressure surface of a turbine blade, would seem to be adequate. High levels of free-stream turbulence superimposed on a free-stream velocity gradient (which occurs within curved channels) was found to cause a cross-stream transport of momentum within the "potential core" of the flow. The total pressure within the "potential core" can thus rise to levels higher than that which occurs at the inlet to the test section. Documentation is presented in two volumes. Volume I contains the text of the report including figures and supporting appendices. Volume II contains data reduction program listings and tabulated data.</p>
